# EXECUTIVE SUMMARY

Home building generates substantial local economic activity, including new income and jobs for residents, and additional revenue for local governments. The National Association of Home Builders has developed a model to estimate the economic benefits. The model captures the effect of the construction activity itself, the ripple impact that occurs when income earned from construction activity is spent and recycles in the local economy, and the ongoing impact that results from new homes becoming occupied by residents who pay taxes and buy locally produced goods and services. In order to fully appreciate the positive impact residential construction has on a community, it's important to include the ripple effects and the ongoing benefits. Since the NAHB model was initially developed in 1996, it has been successfully applied to construction in over 500 projects, local jurisdictions, metropolitan areas, non-metropolitan counties, and states across the country.

This report presents estimates of the metro area impacts of home building in Madison County, Illinois. The comprehensive nature of the NAHB model requires that the local area over which the benefits are spread be large enough to include the places where construction workers live and spend their money, as well as the places where the new home occupants are likely to work, shop, and go for recreation. In practice, this usually means a Metropolitan Statistical Area (MSA) or Metropolitan Division, as defined by the U.S. Office of Management and Budget (OMB). Based on local commuting patterns, OMB has identified the St. Louis MSA as a metro area consisting of eight counties (Bond, Calhoun, Clinton, Jersey, Macoupin, Madison, Monroe, and St. Clair) in Illinois, as well as seven counties (Franklin, Jefferson, Lincoln, St. Charles, St. Louis, Warren, and Washington) plus the independent City of St. Louis in Missouri (see map below).

St. Louis, Missouri and Illinois MSA

In this report, wherever the terms local or St. Louis are used, they refer to the entire metro area. The report presents estimates of the impacts of building 811 single family homes, based on construction activity taking place in Madison County in calendar year 2007.

The NAHB model produces impacts on income and employment in 16 industries and local government, as well as detailed information about taxes and other types of local government revenue. The key results are summarized below. Additional details are contained in subsequent sections.

◆ The estimated one-year metro area impacts of building 811 single family homes in Madison County include

- \$137.4 million in local income,
- \$14.4 million in taxes and other revenue for local governments, and
- 2,275 local jobs.

These are **local impacts**, representing income and jobs for residents of the St. Louis MSA, and taxes (and other sources of revenue, including permit fees) for all local jurisdictions within the metro area. They are also **one-year impacts** that include both the direct and indirect impact of the construction activity itself, and the impact of local residents who earn money from the construction activity spending part of it within the local area.

◆ The additional, annually recurring impacts of building 811 single family homes in Madison County include

- \$22.5 million in local income,
- \$6.6 million in taxes and other revenue for local governments, and
- 418 local jobs.

These are **ongoing, annual local impacts** that result from the new homes being occupied and the occupants paying taxes and otherwise participating in the local economy year after year. In order to fully capture the impact residential construction has on a community, it is important to account for the ongoing benefits as well as the one-time effects.

◆ The above impacts were calculated assuming that new single family homes built in Madison County have an average price of \$233,505; are built on a lot for which the average value of the raw land is \$9,000; require the builder and developer to pay an average of \$8,675 in impact, permit, and other fees to local governments; and incur an average property tax of \$5,634 per year. The property tax payment incorporates a homestead exemption, where property is assessed at one-third of its market value for tax purposes, and the exemption is applied to the assessed amount. This information was obtained from the Greater Gateway Association of REALTORS®, the Madison County Assessors Office, the Madison County Building & Zoning Department, the Madison County Treasurers Office, the Madison County Government Web Site, the Regional Chamber & Growth Association of St. Louis, the State of Illinois Department of Revenue, the U. S. Census Bureau, and Builder and Developer Members of the Home Builders Association of Greater Southwest Illinois.

# IMPACT OF BUILDING 811 SINGLE FAMILY HOMES IN MADISON COUNTY, ILLINOIS

## SUMMARY

*Total One-Year Impact:* Sum of Phase I and Phase II:

Local Income	Local Business Owners' Income	Local Wages and Salaries	Local Taxes <sup>1</sup>	Local Jobs Supported
\$137,390,000	\$40,583,000	\$96,810,000	\$14,433,000	2,275

*Phase I:* Direct and Indirect Impact of Construction Activity:

Local Income	Business Owners' Income	Local Wages and Salaries	Local Taxes <sup>1</sup>	Local Jobs Supported
\$91,794,000	\$25,659,000	\$66,136,000	\$10,083,000	1,480

*Phase II:* Induced (Ripple) Effect of Spending the Income and Taxes from Phase I:

Local Income	Business Owners' Income	Local Wages and Salaries	Local Taxes <sup>1</sup>	Local Jobs Supported
\$45,596,000	\$14,924,000	\$30,674,000	\$4,350,000	795

*Phase III:* Ongoing, Annual Effect that Occurs When New Homes are Occupied:

Local Income	Local Business Owners' Income	Local Wages and Salaries	Local Taxes <sup>1</sup>	Local Jobs Supported
\$22,465,000	\$6,443,000	\$16,021,000	\$6,563,000	418

---

<sup>1</sup> The term local taxes is used as a shorthand for local government revenue from all sources: taxes, fees, fines, revenue from government-owned enterprises, etc...

**IMPACT OF BUILDING 811 SINGLE FAMILY HOMES IN MADISON COUNTY, IL  
PHASE I -- DIRECT AND INDIRECT IMPACT OF CONSTRUCTION ACTIVITY**

**A. Local Income and Jobs by Industry**

Industry	Local Income	Local Business Owners' Income	Local Wages and Salaries	Wages & Salaries per Full-time Job	Number of Local Jobs Supported
Construction	\$63,160,000	\$16,289,000	\$46,871,000	\$46,000	1,024
Manufacturing	\$9,000	\$1,000	\$9,000	\$48,000	0
Transportation	\$152,000	\$21,000	\$131,000	\$38,000	3
Communications	\$943,000	\$288,000	\$655,000	\$70,000	9
Utilities	\$291,000	\$113,000	\$178,000	\$78,000	2

COUNTY, ILLINOIS**

**INCOME, JOBS, AND  
TAXES GENERATED**

**BACKGROUND  
AND A BRIEF  
DESCRIPTION OF  
THE MODEL USED  
TO ESTIMATE THE  
ECONOMIC  
BENEFITS**

The Housing Policy Department of the National Association of Home Builders (NAHB) maintains an economic model that it uses to estimate the local economic benefits of home building. Originally developed in 1996, the model was at first calibrated to a typical metropolitan area using national averages, but from the beginning was capable of being adapted to a specific local economy by replacing key housing market variables. The initial version of the model could be applied to single family construction, multifamily construction, or a combination of the two.

In March of 1997, NAHB began customizing the model to various areas around the country on a routine basis, primarily at the request of its local affiliated associations. As of January 2008, the Housing Policy Department has produced over 500 of these customized reports analyzing residential construction in various metropolitan areas, non-metropolitan counties, and states across the country (see map below).

### **Areas Covered by NAHB Local Impact Studies**

The darkest shading indicates studies that covered metro areas and non-metro counties; the somewhat lighter shading indicates studies that were produced for an entire state.

The reports have analyzed the impacts of specific housing projects, as well as total home building in areas as large as entire states. In 2002, NAHB developed new versions of the model to analyze active adult housing projects and multifamily development financed with the Low-Income Housing Tax Credit. In 2005 a version of the model that analyzes residential remodeling was added to the mix.

Results from NAHB's local impact model have been used by outside organizations such as universities, state housing authorities and affordable housing agencies:

- The Shimborg Center for Affordable Housing at the University of Florida used results from the NAHB model to establish that "the real estate taxes paid year after year are the most obvious long-term economic benefit to the community. Probably the second most obvious long-term economic benefit is the purchases made by the family occupying the completed home." [www.shimberg.ufl.edu/pdfs/Newslett-June02.pdf](http://www.shimberg.ufl.edu/pdfs/Newslett-June02.pdf)
- The Center for Applied Economic Research at Montana State University used "results from an input-output model developed by the National Association of Home Builders to assess the impacts to local areas from new home construction." The results show that "the construction industry contributes substantially to Montana's economy accounting for 5.5 percent of Gross State Product." [www.msubillings.edu/caer/The%20Impact%20of%20Home%20Construction%20in%20Montana.pdf](http://www.msubillings.edu/caer/The%20Impact%20of%20Home%20Construction%20in%20Montana.pdf)
- The Housing Education and Research Center at Michigan State University also adopted the NAHB approach: "The underlying basis for supporting the implementation of this [NAHB] model on Michigan communities is that it provides quantifiable results that link new residential development with commercial and other forms of development therefore illustrating the overall economic effects of residential growth." [www.canr.msu.edu/cm/herc/h5over.html](http://www.canr.msu.edu/cm/herc/h5over.html)
- The Center for Economic Development at the University of Massachusetts found that "Home building generates substantial local economic activity, including income, jobs, and revenue for state and local governments. These far exceed the school costs-to-property-tax ratios. ...these factors were evaluated by means of a quantitative assessment of data from the National Association of Home Builder's Local Impact of Home Building model" [www.donahue.umassp.edu/publications/housing/7-economicco.html](http://www.donahue.umassp.edu/publications/housing/7-economicco.html)
- Similarly, the Association of Oregon Community Development Organizations decided to base its analysis of affordable housing on the NAHB model, stating that "This model is widely respected and utilized in analyzing the economic impact of market rate housing development," and that, compared to alternatives, it "is considered the most comprehensive and is considered an improvement on most previous models." [www.aocdo.org/docs/EcoDevoStudyFinal.pdf](http://www.aocdo.org/docs/EcoDevoStudyFinal.pdf)
- The Boone County Kentucky Planning Commission included results from the NAHB model in its 2005 Comprehensive Report. The Planning Commission used values from the impact model to quantify the increase in local income, taxes, revenue, jobs, and overall local economic impacts in the Metro Area as a result of new home construction. <http://www.boonecountyky.org/pc/2005CompPlan.aspx>

## A Brief Description of the Model

The NAHB model is divided into three phases. Phases I and II are one-time effects. Phase I captures the effects that result directly from the construction activity itself and the local industries that contribute to it. Phase II captures the effects that occur as a result of the wages and profits from Phase I being spent in the local economy. Phase III is an ongoing, annual effect that includes property tax payments and the result of the completed unit being occupied.

### ***Phase I: Local Industries Involved in Home Building***

**The jobs, wages, and local taxes (including permit, utility connection, and impact fees) generated by the actual development, construction, and sale of the home.** These jobs include on-site and off-site construction work as well as jobs generated in retail and wholesale sales of components, transportation to the site, and the professional services required to build a home and deliver it to its final customer.

### ***Phase II: Ripple Effect***

**The wages and profits for local area residents earned during the construction period are spent on other locally produced goods and services.** This generates additional income for local residents, which is spent on still more locally produced goods and services, and so on. This continuing recycling of income back into the community is usually called a *multiplier* or *ripple* effect.

### ***Phase III: Ongoing, Annual Effect***

**The local jobs, income, and taxes generated as a result of the home being occupied.** A household moving into a new home generally spends about three-fifths of its income on goods and services sold in the local economy. A fraction of this will become income for local workers and local businesses proprietors. In a typical local area, the household will also pay 1.25 percent of its income to local governments in the form of taxes and user fees, and a fraction of this will become income for local government employees. This is the first step in another set of economic ripples that cause a permanent increase in the level of economic activity, jobs, wages, and local tax receipts.

## **Modeling a Local Economy**

The model defines a local economy as a collection of industries and commodities. These are selected from the detailed benchmark input-output tables produced by the U.S. Bureau of Economic Analysis. The idea is to choose goods and services that would typically be produced, sold, and consumed within a local market area. Laundry services would qualify, for example, while automobile manufacturing would not. Both business-to-business and business-to-consumer transactions are considered. In general the model takes a conservative approach and retains a relatively small number of the available industries and commodities. Of the roughly 600 industries and commodities provided in the input-output files, the model uses only 87 commodities and 89 industries.

The design of the model implies that a local economy should include not only the places people live, but also the places where they work, shop, typically go for entertainment, etc. This corresponds reasonably well to the concepts of Metropolitan Statistical Areas and Metropolitan Divisions, areas defined by the U.S. Office of Management and Budget based on local commuting patterns. Outside of these officially defined metropolitan areas, NAHB has determined that a county will usually satisfy the model's requirements.

For a particular local area, the model adjusts the indirect business tax section of the national input-output accounts to account for the fiscal structure of local governments in the area. The information used to do this comes primarily from the U.S. Census Bureau's Census of Governments. Wages and salaries are extracted from the employee compensation section of the input-output accounts on an industry-by-industry basis. In order to relate wages and salaries to employment, the model incorporates data on local wages per job published by the Bureau of Economic Analysis.

## **Phase I: Construction**

In order to estimate the local impacts generated by home building, it is necessary to know the sales price of the homes being built, how much raw land contributes to the final price, and how much the builder and developer pay to local area governments in the form of permit, utility connection, impact, and other fees. This information is not generally available from national sources and in most cases must be provided by representatives from the area in question who have specialized knowledge of local conditions.

The model subtracts raw land value from the price of new construction and converts the difference into local wages, salaries, business owners' income, and taxes. This is done separately for all 95 local industries. In addition, the taxes and fees collected by local governments during the construction phase generate wages and salaries for local government employees. Finally the number of full time jobs supported by the wages and salaries generated in each private local industry and the local government sector is estimated.

**Phase II: The Construction Ripple**

Clearly, the local residents who earn income in Phase I will spend a share of it. Some of this will escape the local economy. A portion of the money used to buy a new car, for example, will become wages for autoworkers who are likely to live in another city, and increased profits for stockholders of an automobile manufacturing company who are also likely to live elsewhere. A portion of the spending, however, will remain within, and have an impact on, the local economy. The car is likely to be purchased from a local dealer and generate income for a salesperson who lives in the area, as well for local workers who provide cleaning, maintenance, and other services to the dealership. Consumers also are likely to purchase many services locally, as well as to pay taxes and fees to local governments.

This implies that the income and taxes generated in Phase I become the input for additional economic impacts analyzed in what we call Phase II of the model. Phase II begins by estimating how much of the added income households spend on each of the local commodities. This requires detailed analysis of data from the Consumer Expenditure (CE) Survey, which is conducted by the U.S. Bureau of Labor Statistics primarily for the purpose of determining the weights for the Consumer Price Index. The analysis produces household spending estimates for 55 local commodities. The remainder of the 87 local commodities enter the model only as business-to-business transactions.

The model then translates the estimated local spending into local business owners' income, wages and salaries, jobs, and taxes. This is essentially the same procedure applied to the homes sold to consumers in Phase I. In Phase II, however, the procedure is applied simultaneously to 56 locally produced and sold commodities.

In other words, the model converts the local income earned in Phase I into local spending, which then generates additional local income. But this in turn will lead to additional spending, which will generate more local income, leading to another round of spending, and so on. Calculating the end result of these economic is a straightforward exercise in mathematics.

**Phase III: The Ongoing Impacts**

Like Phase II, Phase III involves computing the sum of successive ripples of economic activity. In Phase III, however, the first ripple is generated by the income and spending of a new household (along with the additional property taxes local governments collect as a result of the new structure). This does not necessarily imply that all new homes must be occupied by households moving in from outside the local area. It may be that an average new-home household moves into the newly constructed unit from elsewhere in the same local area, while average existing-home household moves in from outside to occupy the unit vacated by the first household. Alternatively, it may be that the new home allows the local area to retain a household that would otherwise move out of the area for lack of suitable housing.

In any of these cases, it is appropriate to treat a new, occupied housing unit as a net gain to the local economy of one household with average characteristics for a household that occupies a new home. This reasoning is often used, even if unconsciously, when it is assumed that a new

home will be occupied by a household with average characteristics—for instance, an average number of children who will consume public education.

To estimate the impact of the net additional households, Phase III of the model requires an estimate of the income of the households occupying the new homes. The information used to compute this estimate comes from several sources, but primarily from an NAHB statistical model based on decennial census data. Phase III of the local impact model then estimates the fraction of income these households spend on various local commodities. This is done with CES data and is similar to the procedure described under Phase II. The model also calculates the amount of local taxes the households pay each year. This is done with Census of Governments data except in the case of residential property taxes, which are treated separately, and for which specific information must usually be obtained from a local source. Finally, a total ripple effect is computed, using essentially the same procedure outlined above under Phase II.

The details covered here provide only a brief description of the model NAHB uses to estimate the local economic benefits of home building. For a more complete description, see the technical documentation at the end of the report. For additional information about the model, or questions about applying it to a particular local area, contact one of the following in NAHB's Housing Policy Department:
